

## New York Academy of Medicine Collection of International Medical Theses

### Box 24:1:1

### Beirut, Lebanon

(H00501865%)

The following titles are part of the New York Academy of Medicine Collection of International Medical Theses, housed at the University of North Carolina at Chapel Hill's Health Sciences Library. The collection consists of tens of thousands of post-1801 theses in multiple languages from leading medical schools throughout the world. Europe is well represented, with many theses originating from universities in Germany, France, the Netherlands, Spain, Sweden, and Switzerland. Countries with lesser quantities in the collection include Argentina, Brazil, Chile, Algeria, Indonesia, and others.

For a complete listing of titles or to request items, please refer to the finding aid:

Epidemic of Dengue at Beirut

Year 1927

---

Graduation Thesis

Presented to the Faculty of the School of Medicine

for the degree of M. D.

*Beirut*

by

M. Kan'an

June 1st, 1928

in 1902, after a study of 100 cases of dengue in Syria, Dr. Gubler indicated the fact that the disease is transmitted by the Aedes mosquito. He then concluded that the causative agent must be in the blood. After examination of the blood taken from the finger or from eruptive lesions, Dr. Gubler believes to have small and unsegmented intracorporeal parasites resembling

THE LIVER AS A DETOXICATING ORGAN

INTRODUCTORY.

During the past few years, a great deal of research work has been done in the liver, and our knowledge of its various functions is increasing. However, there is a great deal about it still unknown, which affords the research worker a splendid field for investigation. Among the various problems that the liver presents, of special interest is its detoxicative function. It is impressive to a service that this organ renders the organism in this connection.

T H E S I S

ON

THE LIVER AS A DETOXICATING ORGAN

The literature is full of experimental work about various phases of detoxication by the liver, but when it comes to textbooks, only a short space is allotted to this subject. The purpose of this study is to fill the gap from the voluminous literature concerning this function. That this study affords opportunity for doing actual experimental work on animals adds to its value, and justifies the choice of the subject.

HISTORICAL.

The liver is one of the organs that were the first to be studied. It was used in divination by the Assyrians long before the dawn of Anatomy. It was so respected, probably on account of its extreme vascularity, seeing that blood was considered by the early races as the seat of life.

Up to the fifteenth century, however, what was known concerning it was for the most part based upon mythology. The new era in hepatology began in the seventeenth century when the Englishman Glisson discovered the capsula fibrosa hepatis, and published the first satisfactory description of the anatomy of the liver.

In 1666, Malpighi taught that the liver is a gland which secretes bile. In 1693, Saunders published his treatise on the structure, economy and diseases of the liver. In 1791, Morgagni at the age of 79 published his treatise on the condition now known as cirrhosis of the liver. In 1795, Baillie gave the first description of the liver. In 1843, Clark published his treatise on the liver, which led to his discovery of the glycogenic function of the liver.
